

ABSTRACT

1 A system enables tender of payment manually (e.g., cash, check, etc.) for transactions
2 conducted over a network (e.g., the Internet). The system includes one or more computer
3 systems each located at a corresponding agent site, one or more merchant systems and a server
4 computer system in communication with the agent and merchant systems. The server system
5 accesses the appropriate merchant network or web site in response to transaction selection
6 information received from the agent system, and translates those web pages for transmission
7 to the agent system. The server computer system further receives the required transaction
8 information from the agent system and processes the transaction information for transference
9 to the particular merchant web site. In addition, the server system enters credit card
10 information of a provider of the transaction service within the transaction payment
11 information for transference to the merchant system in order to tender payment for the
12 network transaction.
